# Preparing for physics with ATLAS experiment at LHC

# Machine start up scenario

First dipole in the tunnel - March '05

Magnets in place

- ~ January 2007 - March 2007 machine cool-down
- ~ April 2007 : start machine commissioning (in part with single beam)
- ~ July 2007 : two beams in the machine (first collisions)
  - start with  $L = 6 \cdot 10^{31} \text{ cm}^{-2} \text{ s}^{-1}$
  - 4 months with up to  $L > 5 \cdot 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$
  - 2-3 months shut-down
  - 7 months of physics run up to  $L = 2 \cdot 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$
- 6 months at  $L_{\text{peak}} = 10^{32} (10^{33}) \text{ cm}^{-2} \text{ sec}^{-1}$  at 50% efficiency makes 1(10) fb<sup>-1</sup>

# Which detector the first year?

2 pixel layers/discs instead of 3?

TRT acceptance over  $|\eta| < 2.0$  instead of 2.4

Deferrals of the high-level Trigger/DAQ processors  
LVL1 output rate limited to  $\sim 40\text{kHz}$  instead of  $75\text{kHz}$

Impact on physics visible but acceptable

Main loss: B-physics programme strongly reduced (single  $\mu$  threshold 14-20 GeV)

Length :  $\sim 45\text{ m}$

Radius :  $\sim 12\text{ m}$

Weight :  $\sim 7000\text{ tons}$

Electronic channels :  $\sim 10^8$

• Tracking ( $|\eta| < 2.5$ ,  $B=2\text{T}$ ) :

-- Si pixels and strips

-- Transition Radiation Detector ( $e/\pi$  separation)

• Calorimetry ( $|\eta| < 5$ ) :

-- EM : Pb-LAr

-- HAD: Fe/scintillator (central), Cu/W-LAr (fwd)

• Muon Spectrometer ( $|\eta| < 2.7$ ) :

air-core toroids with muon chambers

# Commissioning in the cavern

---

**The last Barrel Toroid coil was moved into position on 25<sup>th</sup> August and the structure was released from the external supports on 29<sup>th</sup> September**

**The barrel LAr and Tile calorimeters have been ready since some time in the cavern in their 'garage Position', moved into their final position on November 4th**

**November 4<sup>th</sup> Night: Calorimeter barrel after its move to the center of the ATLAS detector**

# The Physics Programme

---

- **Understand the origin of particle masses and EWSB mechanism**
  - look for Higgs(es) from the present LEP limits up to  $\sim 1$  TeV
- **Look for physics beyond the SM (hierarchy, quantum gravity)**
  - **SUSY models: explore masses up to  $\sim 2$  TeV**
  - **other scenarios: additional W/Z bosons up to  $M \sim 5$  TeV, leptoquarks, extra-dimension, technicolor...**
- **Perform precision measurements beyond sensitivity of previous experiments**
  - **W, top**
  - **QCD**
  - **B-physics and CP violation**

# Which detector performance on day one?

A few educated guesses *based on the test beam results and simulation studies*

	Expected performance day 1	Final goals	Physics samples to improve (examples)
ECAL uniformity	~ 1%	0.7%	Minimum bias, $Z \rightarrow ee$
e/ $\gamma$ scale	1-2%	0.1%	$Z \rightarrow ee$
HCAL uniformity	2-3%		Single pions, QCD jets
Jet scale	< 10%	1%	$Z(\rightarrow ll)+1j$ , $W \rightarrow jj$ in $tt$
Tracking alignment	20-500 $\mu\text{m}$ in $R\phi$ ?	5 $\mu\text{m}$	generic tracks, isolated $\mu$ , $Z \rightarrow \mu\mu$

Large<sup>(\*)</sup> statistics at beginning (events on tape for **1 fb<sup>-1</sup>**), then face systematics....

E.g. tracking alignment : 100  $\mu\text{m}$  (1 month)  $\rightarrow$  20  $\mu\text{m}$  (4 month)  $\rightarrow$  5  $\mu\text{m}$  (1 year)

# To achieve the detector goal performance?

→ Stringent construction requirements and quality controls (piece by piece...)

→ Equipped with redundant calibration/alignment hardware systems

→ Prototypes and part of final modules extensively tested with test beams  
(allows also validation of Gean4 simulation)

→ In situ calibration at the collider

(accounts for material, global detector, B-field, long-range miss-calibrations and miss-alignments)  
includes:

- cosmic runs:  
end 2006 – beg 2007 during machine cool-down
- beam-gas events:  
beam-halo muons during single-beam period
- calibration with physics samples  
(e.g.  $Z \rightarrow ee, \mu\mu, \tau\tau$ , etc.)

# As example : LAr electromagnetic calorimeter

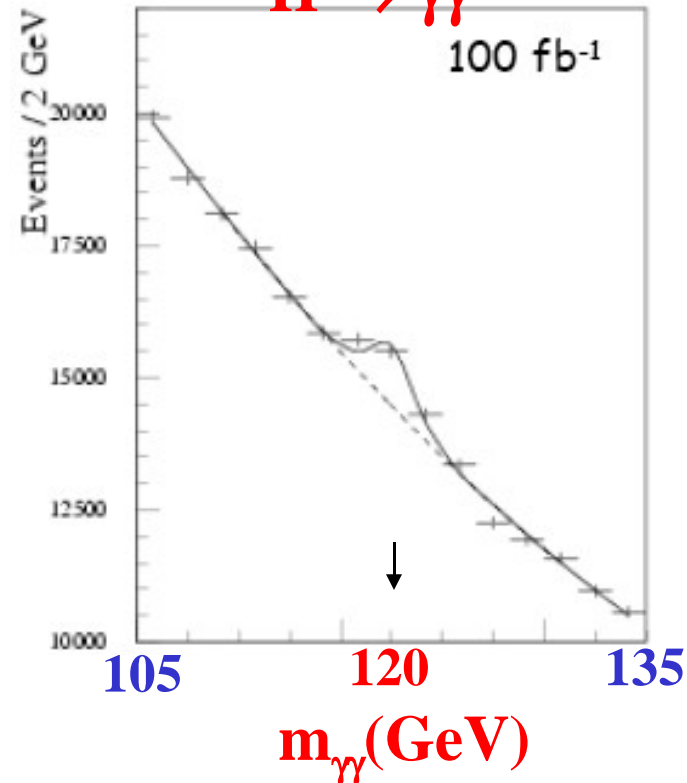

$H \rightarrow \gamma\gamma$  needs mass resolution  $\sim 1\%$

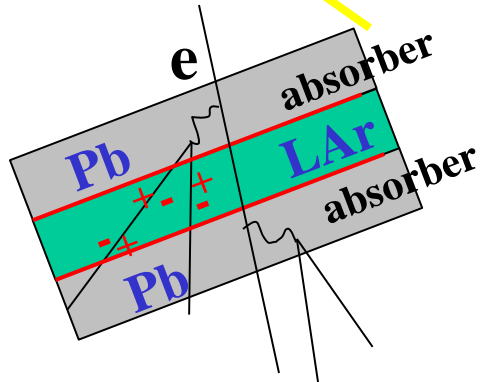

e.m. calorimeter energy response uniformity  $\leq 0.7\%$  over  $|\eta| < 2.5$

$H \rightarrow \gamma\gamma$

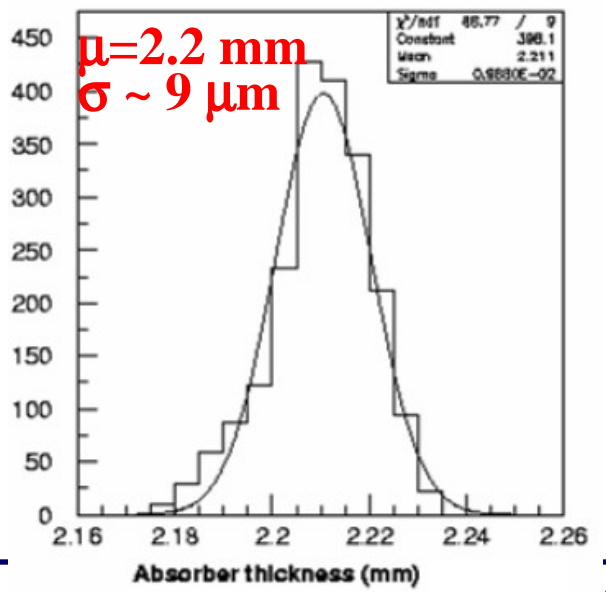

# EM Endcap : Construction requirements

End-cap wheel in vertical position (24/6/03)

- To keep energy response uniform to  $\sim 0.2-0.3\%$  thickness of Pb absorber plates must be uniform to  $\sim 0.5\%$  ( $\sim 10 \mu\text{m}$ )
- Thickness of 1536 plates for EM endcap  $\longrightarrow$  measured with ultrasounds during construction

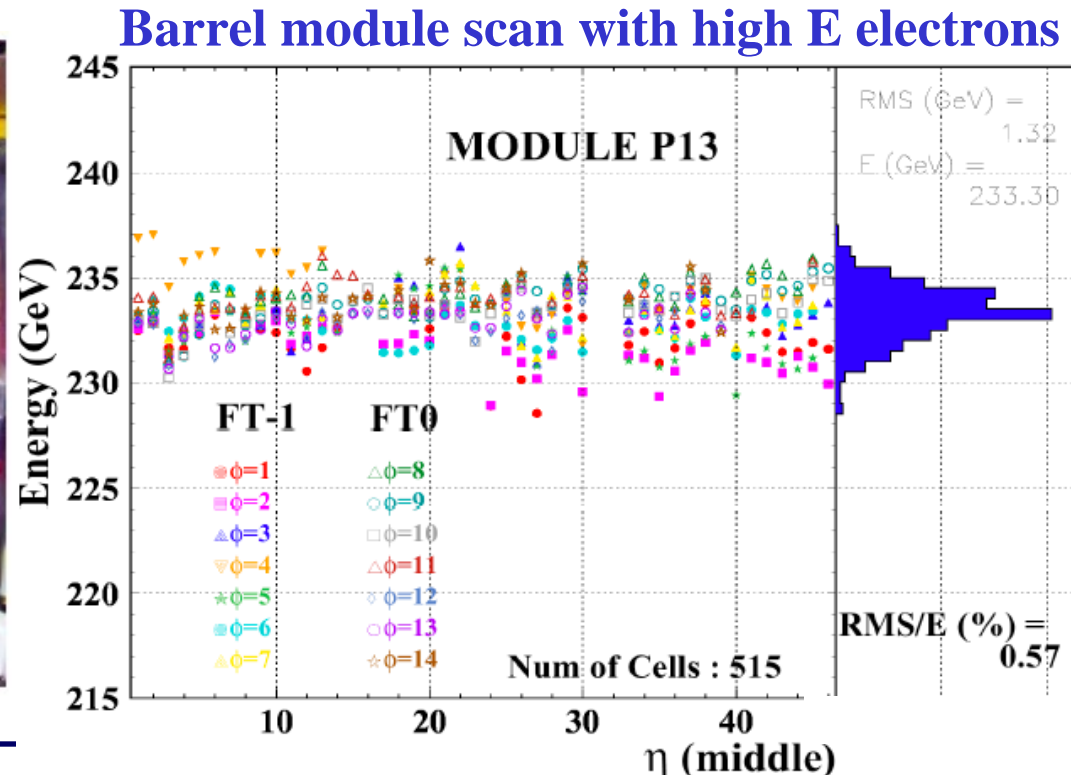

# EM Barrel: 1999-2002 test beam

- Test of 4(out of 32) barrel, 3(out of 16) end-cap final modules
- Required **uniformity** in regions of size  $\Delta\eta \times \Delta\phi = 0.2 \times 0.4 \sim 0.5\%$  (440 regions in the full ECAL)

# Toward Physics: 2004 ATLAS Combined Test Beam

~ O(1%) of ATLAS tested on CERN H8 beam line

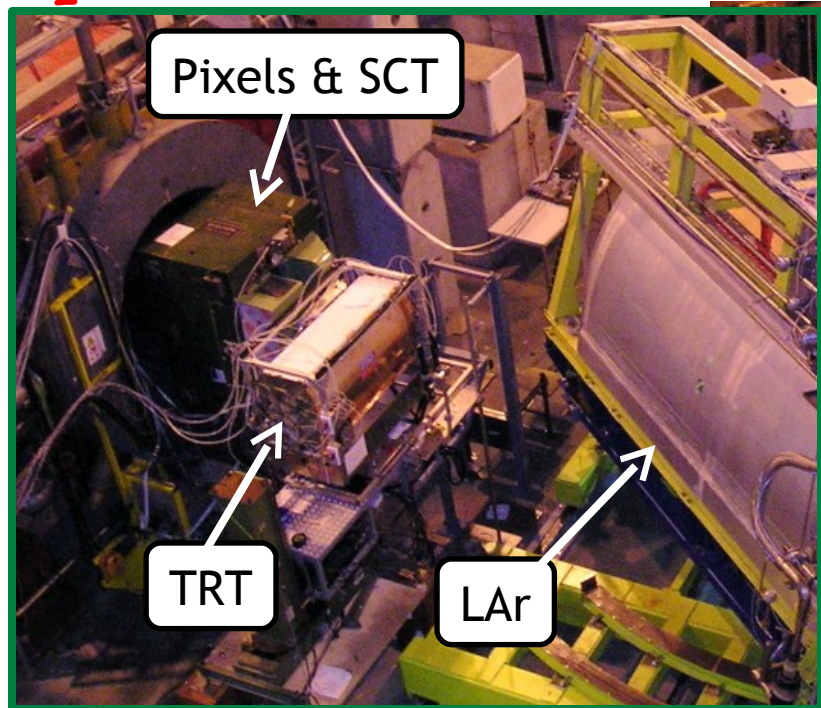

Geant4 simulation  
of test-beam set-up

- «final» detector modules
- «final» electronics monitoring
- ATLAS software to analyze data.

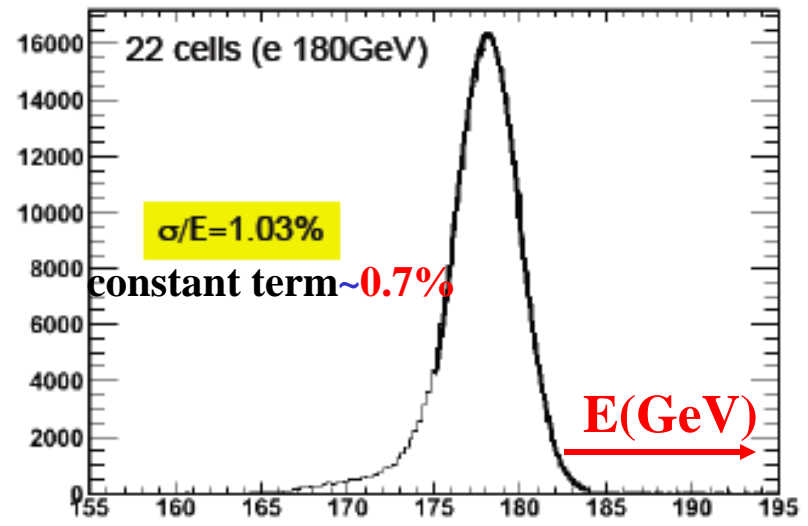

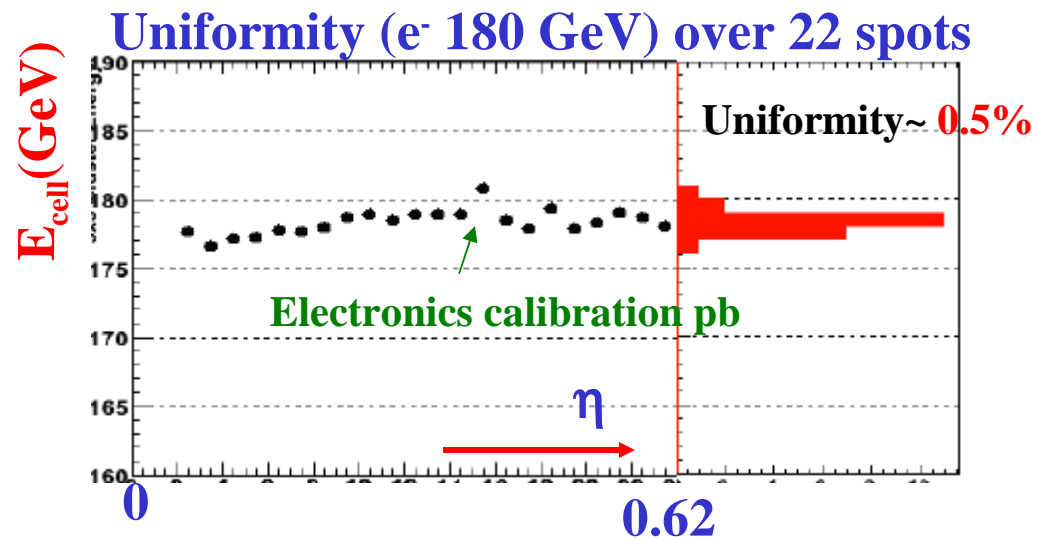

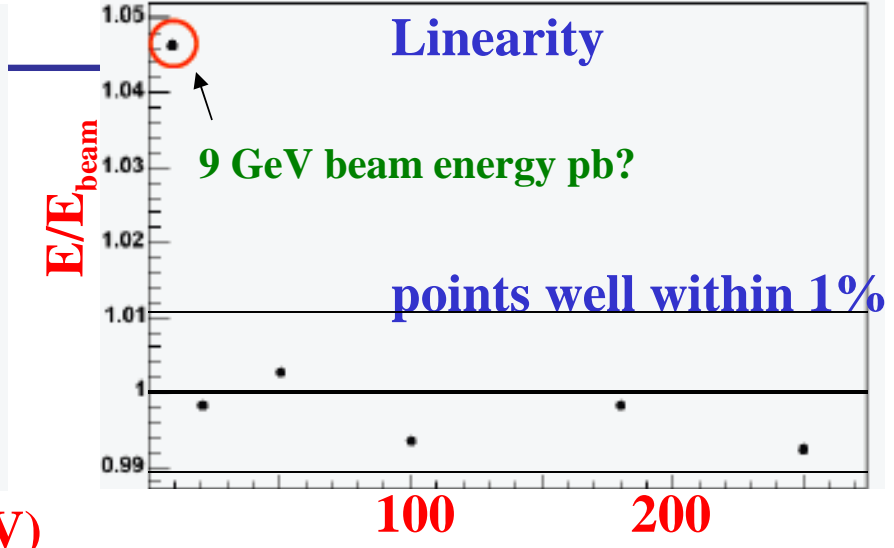

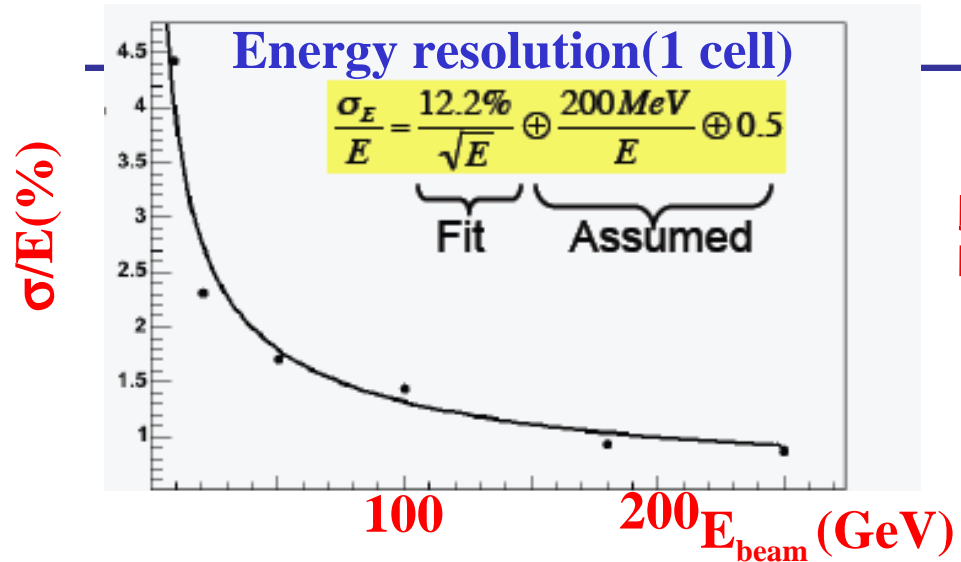

# Toward Physics: 2004 ATLAS Combined Test Beam

- 90 millions events collected (~ 4.5 TB)
- $e^\pm, \pi^\pm, \mu^\pm, \gamma$  @ various energies,  $B=0 \rightarrow 1.4$  T

# CTB: **electron studies** (preliminary results)

- **Work in progress to understand the material in the beam line**

# Toward Physics : 'In situ' commissioning

---

- Cosmic muons (from 'now' till begin 2007):

Debugging, dead channels, prel. alignment/calibration, synchronization...

Rates : ~ **0.5 Hz** 'pass by origin'. First **InnerTracker(IT)** alignment  
tenth of  $\mu\text{m}$  statistical precision in some parts of **IT**  
useful for **LAr EM** studies (timing, uniformity ...)

**Beam gas (7 TeV p on residual gas at rest):**

Rates: **25 Hz** of reconstructed tracks ( $p_t > 1 \text{ GeV } z < 20 \text{ cm}$ )

Tracking alignment (100  $\mu\text{m}$  or better)

Timing

**Beam halo (straight tracks accompanying the beam ):**

Rates: **10 Hz** with  $E > 100 \text{ GeV}$

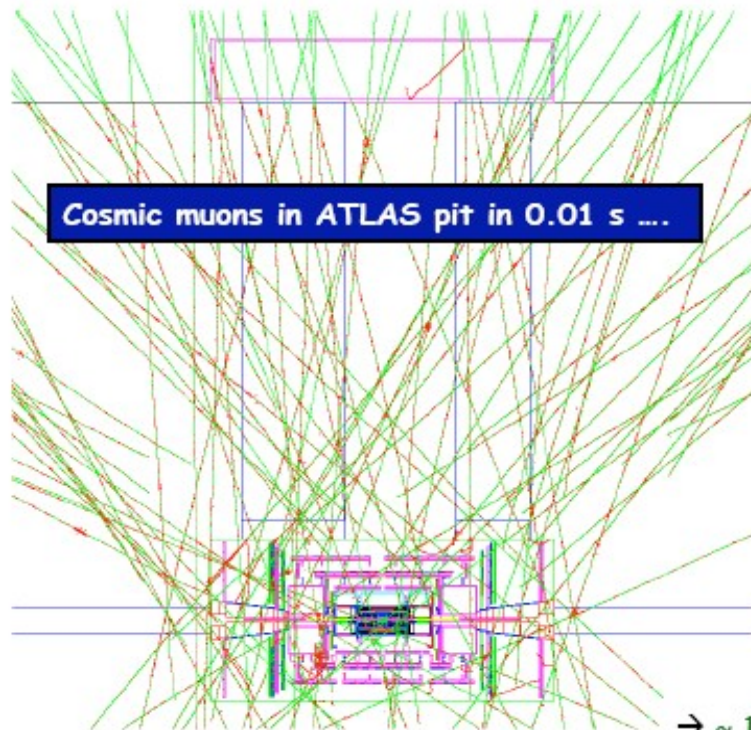

Timing

- Calibration/alignment with (1rst) collisions

---

# Cosmic muons in ATLAS cavern

## ③ Check calibration with **cosmic muons**:

From full simulation of ATLAS (including cavern, overburden, surface buildings) + measurements with scintillators in the cavern:

Through-going muons ~ 25 Hz  
(hits in ID + top and bottom muon chambers)

Pass by origin ~ 0.5 Hz  
( $|z| < 60$  cm,  $R < 20$  cm, hits in ID)

Useful for ECAL calibration ~ 0.5 Hz  
( $|z| < 30$  cm,  $E_{\text{cell}} > 100$  MeV,  $\sim 90^\circ$ )

→  $\sim 10^6$  events in  $\sim 3$  months of data taking  
→ enough for initial detector shake-down  
(catalog problems, gain operation experience,  
some alignment/calibration, detector synchronization, ...)

F. Gianotti, La Thuile, 5/3/2005

# Cosmic muons with ATLAS TRT

Cosmics recorded in the barrel TRT (on the surface)

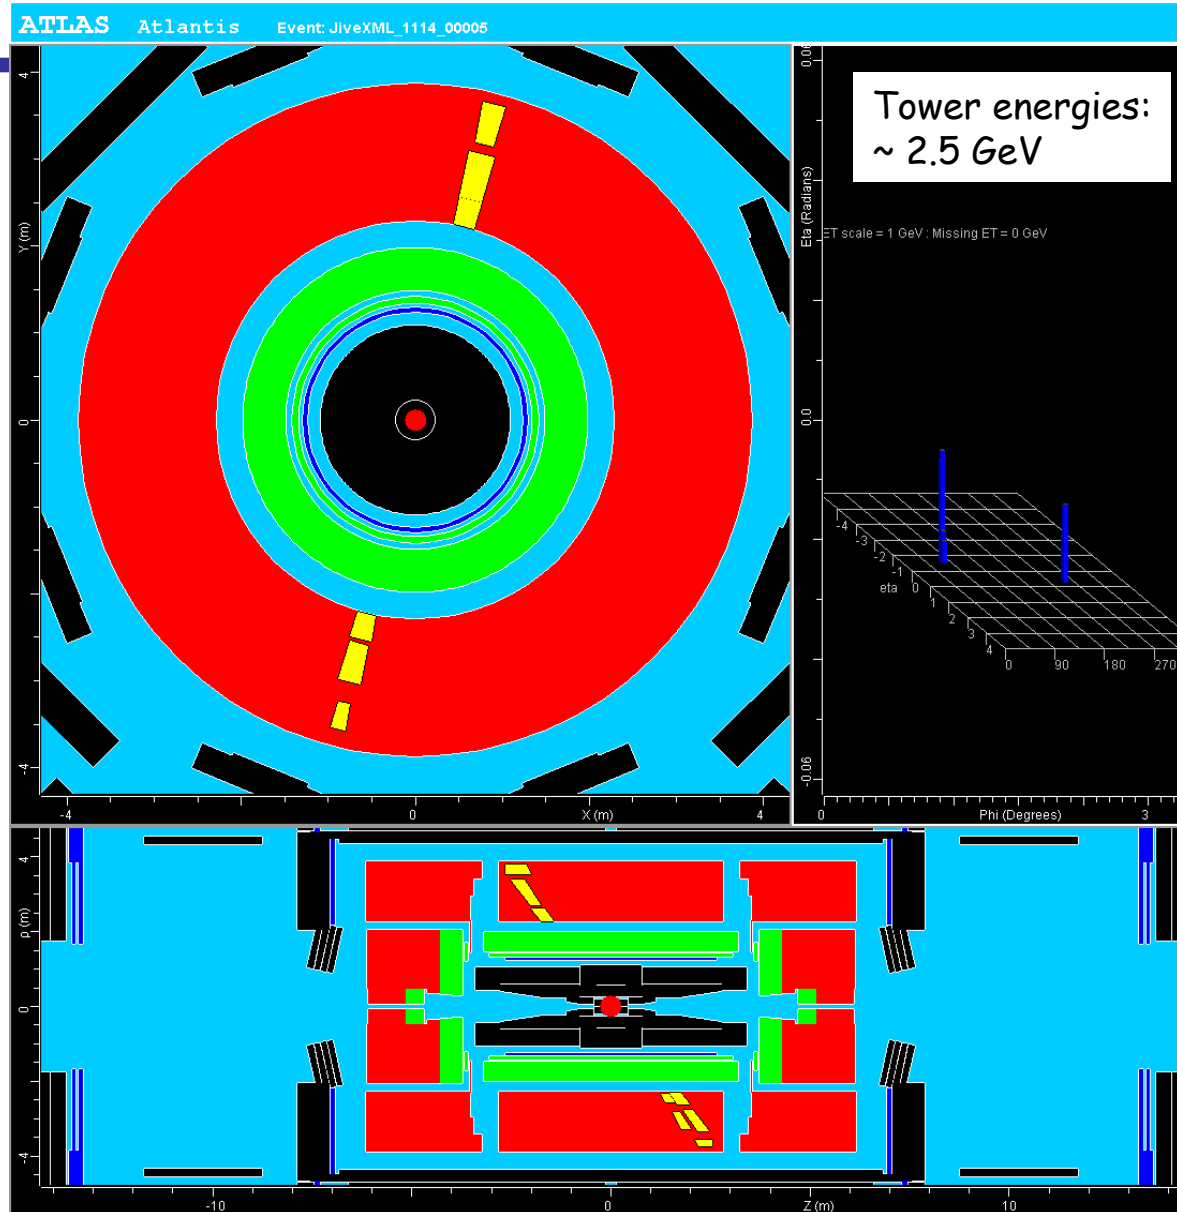

Integrated end-cap TRT wheels of the initial detector for one side

# Cosmic muons with TileCal

- First cosmic muons recorded by hadron Tilecal calorimeter on June 20th 2005
- Spring 2006 : calorimeters+  $\mu$  chambers (final position)
- April 2007 : global cosmic run

# Single beam operation

- **Beam-gas collisions:**
  - essentially boosted minimum-bias events, low- $p_T$  particles
  - Rate :  $\sim 2500$  interactions/m/s

**Beam-gas**

Need dedicated scintillator trigger  
(beam halo @ small R & beam-gas)

- **Beam-halo:**  
Straight tracks

**Beam Halo**

# Physic goals and potential in the first year

1 fb<sup>-1</sup> (10 fb<sup>-1</sup>) ≡ 6 months at 10<sup>32</sup> (10<sup>33</sup>) cm<sup>-2</sup>s<sup>-1</sup>  
 at 50% efficiency → may collect  
 several fb<sup>-1</sup> per experiment by end 2008

Channels (examples ...)	Events to tape for 10 fb <sup>-1</sup> (per experiment)
W → μ ν	7 × 10 <sup>7</sup>
Z → μ μ	1.1 × 10 <sup>7</sup>
tt → W b W b → μ ν + X	0.08 × 10 <sup>7</sup>
QCD jets p <sub>T</sub> >150	~ 10 <sup>7</sup>
Minimum bias	~ 10 <sup>7</sup>
$\tilde{g}\tilde{g}$ m = 1 TeV	10 <sup>3</sup> - 10 <sup>4</sup>

1PB of data per year  
 → challenging for software and computing

} assuming 1%  
 of trigger  
 bandwidth

- Already at first year large statistics expected from
- known SM processes → [understand detector](#) at 14 TeV
  - **several New Physics scenarios**

Note: overall event statistics limited by ~ 100Hz rate to storage  
 ~ 10<sup>7</sup> events to tape every 3 days assuming 30% data taking efficiency

# Physic goals

---

## Goal #1

Understand and calibrate detector and trigger in situ using well-known physics

$Z \rightarrow ee, \mu\mu$       tracker, ECAL, Muon chambers calib & alignment  
 $tt \rightarrow blv bjj$       jet scale, b-tagging

Understand basic SM physics at 14 TeV  $\rightarrow$  also first check of Monte Carlos  
measure cross-sections for eg. minimum bias, W, Z, tt, QCD jets (to 10-20%),  
look at basic event features, first constraints of PDF's  
measure top mass (to 5-7 GeV)  $\rightarrow$  give feedback on detector performance  
Note: statistical error negligible after few weeks run

## Goal #2

Prepare the road to discovery:

- measure background to New Physics: eg. tt and W/Z+jets
- look at specific control samples for individual channels:  
eg. ttjj with  $j \neq b$  “calibrates” ttbb irreducible background to ttH  $\rightarrow$  ttbb

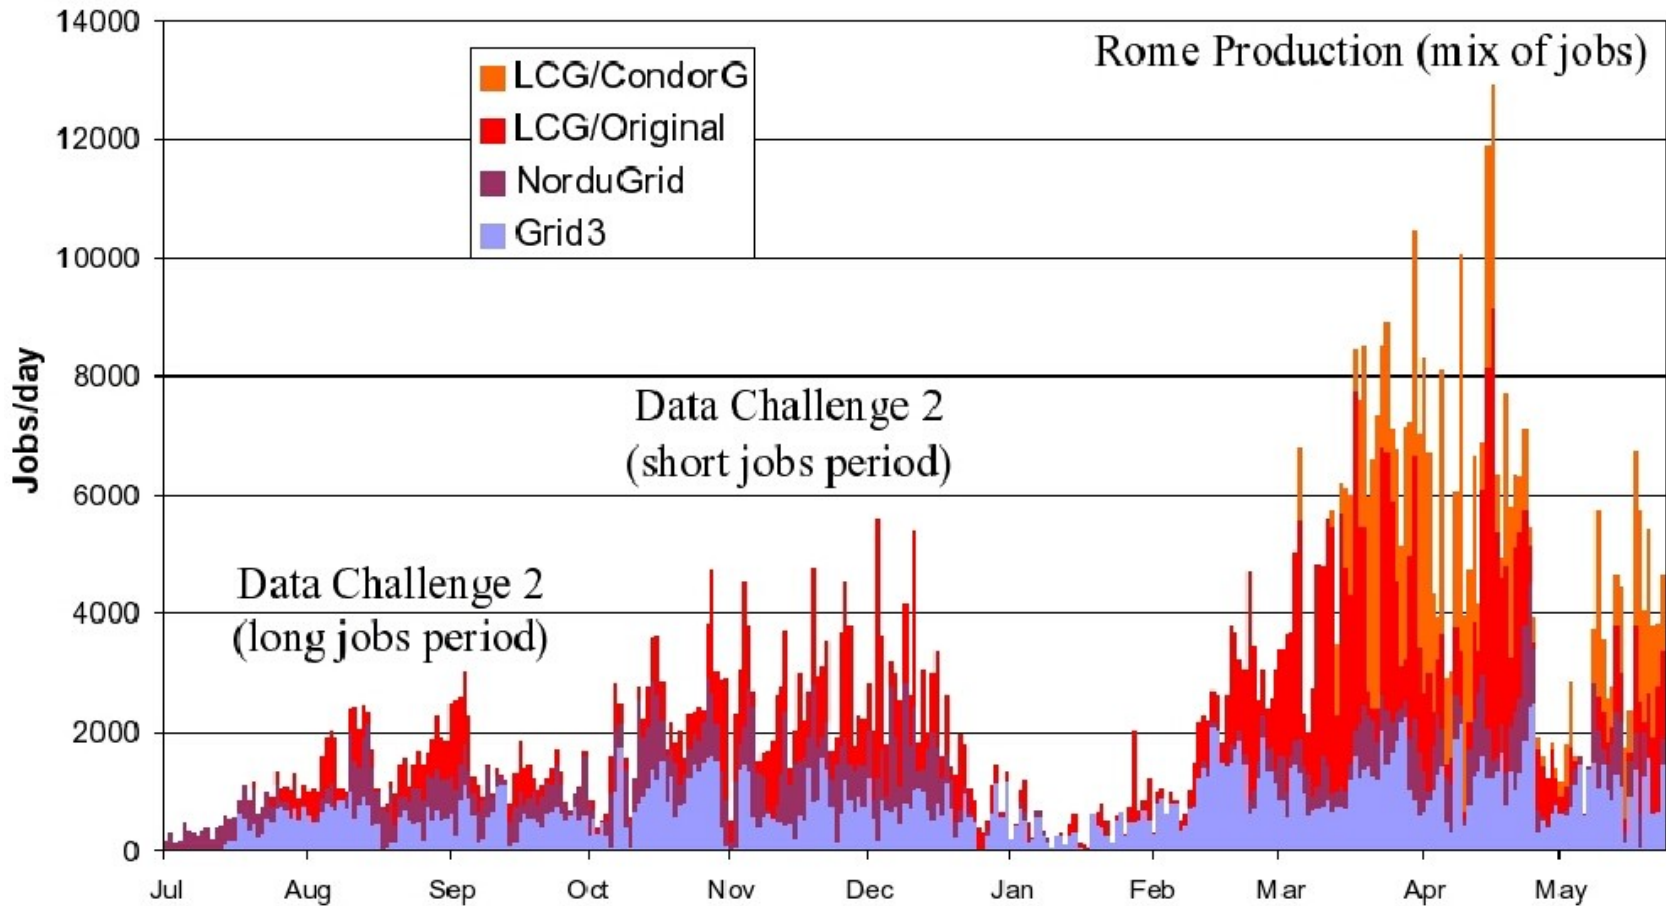

## Goal #3

Look for New Physics potentially accessible in first year (SUSY, Higgs,...)

# Physics simulation work on the grid for the Rome Physics WS

This is the first successful use of the grid by a large user community in ATLAS

Very instructive comments from the user feedback have been presented at the recent ATLAS Physics Workshop (obviously this was one of the main themes and purposes of the meeting)

# “Early physics”: LHC kinematic regime

Underlying Event

- Kinematic regime for LHC much broader than currently explored

## Tests of QCD

- test of DGLAP evolution
- improve information on high  $x$ -gluon distribution
- At  $Q \sim \text{TeV}$  New Physics cross-section predictions dominated by **high- $x$**  gluon uncertainties
- At  $Q \sim M_w$  theoretical predictions for LHC dominated by **low- $x$  gluon** uncertainties

# “Early physics”: Minimum Bias (MB) & Underlying Events(UE)

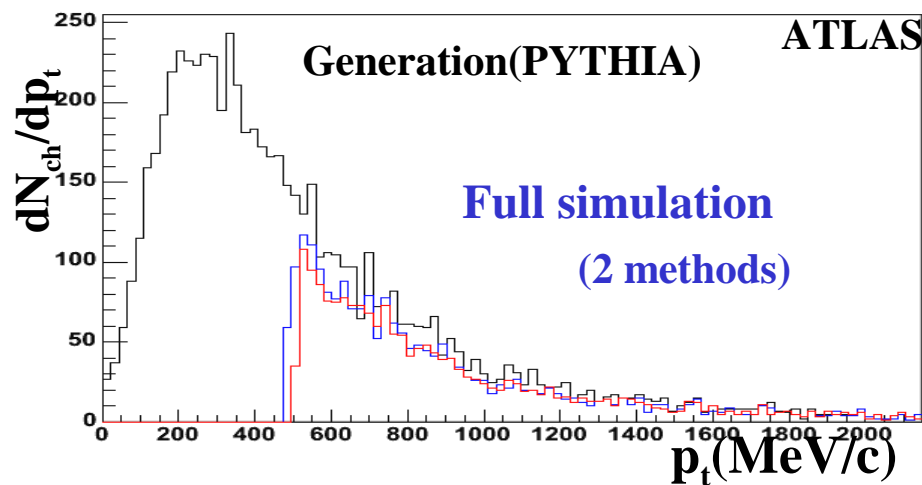

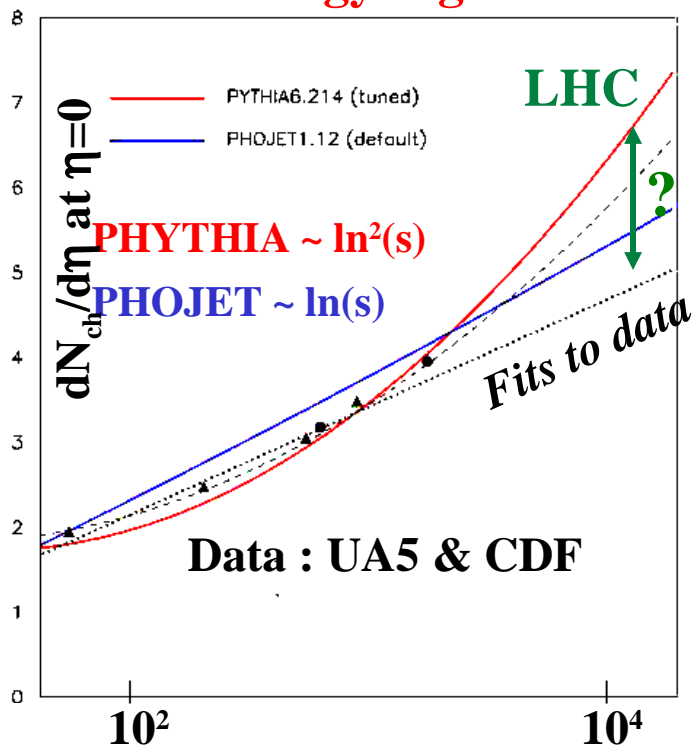

Use ‘**MB trigger**’ ( $\sim 70 \text{ mb} \Rightarrow$  for  $10 \text{ fb}^{-1} \sim 10^7$  evts on tape) and ‘**jet trigger**’ to :

- Understand Pile Up & low  $p_T$  jets (fw jet tag & jet veto, etc...)
- Tune UE model ( $\sim$  soft part of the pp interaction not described by PQCD)

Measure:  $dN_{ch}/d\eta$  ,  $dN_{ch}/dp_t$  , ...  
need Inner Tracker

( $N_{ch}$  = number of charged particles)

**New energy regime !!**

Special runs with lower solenoid field to get better efficiency for  $p_t \sim 200 \text{ MeV}$

# “Early physics”: gauge bosons W and Z

---

- **Best known cross sections at LHC: NNLO in PQCD**  
(1% scale uncertainty)  
input e.w. param. well known

- **Uncertainties from PDF, luminosity (L)**
- **Tests of SM predictions :  $R = d\sigma/dy(W^-) / d\sigma/dy(W^+)$  } not so sensitive to PDF & L  
W Asymmetry } (ratios)**
- **Constraining PDF: uncertainties on present PDF : 4-8%**  
ATLAS measurement of **e** (from  $W \rightarrow e \nu$ ) **angular distribution** provide  
discrimination between different PDF if experimental precision  $\sim$  **3-5%**
- **For L measurement: detector systematics:**  
**Trigger, acceptance, identification efficiency and background**

# “Early physics”: Pdf determination using W bosons

W<sup>+</sup> and W<sup>-</sup> Rapidity

- Uncertainty in pdf transferred to sizeable variation in rapidity distribution electrons
- Limited by **systematic uncertainties**
  - To discriminate between conventional PDF sets we need to achieve an **accuracy ~3%** on rapidity distributions.

Error boxes:  
The full PDF  
Uncertainties

CTEQ61 (MC@NLO)  
MRST02 (MC@NLO)  
ZEUS02 (MC@NLO)  
MRST03 (Herwig+k-Factors)

Stat ~6 hours  
at low Lumi.

# “Early physics”: top signal & mass

Use gold-plated  $t\bar{t} \rightarrow bWbW \rightarrow bl\nu bjj$  channel

( $\sigma_{t\bar{t}} \sim 830 \text{ pb} \Rightarrow 10^7 \text{ tt/y at } 10^{33}$ )

Very simple selection:

- isolated lepton (e,μ)  $p_T > 20 \text{ GeV}$
- exactly 4 jets  $p_T > 40 \text{ GeV}$
- no kinematic fit
- no b-tagging required (pessimistic, assumes trackers not yet understood)

Time	Events at $10^{33}$	Stat. error $\delta M_{\text{top}}$ (GeV)	Stat. error $\delta\sigma/\sigma$
1 year	$3 \times 10^6$	0.1	0.2%
1 month	$7 \times 10^4$	0.2	0.4%
1 week	$2 \times 10^3$	0.4	2.5%

Top signal visible in few days also with simple selection and no b-tagging

Cross-section to  $\sim 20\%$  (10% from luminosity)

Top mass to  $\sim 7\text{GeV}$  (assuming b-jet scale to 10%)

Get feedback on detector performance:

$m_{\text{top}}$  wrong  $\rightarrow$  jet scale?

gold-plated sample to commission b-tagging

*Understand the interplay between using the top signal as tool to improve the understanding of the detector (b-tagging, jet E scale, ID, etc..) and top precision measurements*

# Detector commissioning with top events

■ Now also exploit correlation between  $m(\text{top}_{\text{had}})$  and  $m(W_{\text{had}})$

○ Show  $m(\text{top}_{\text{had}})$  only for events with  $|m(\text{jj})-m(W)| < 10 \text{ GeV}$

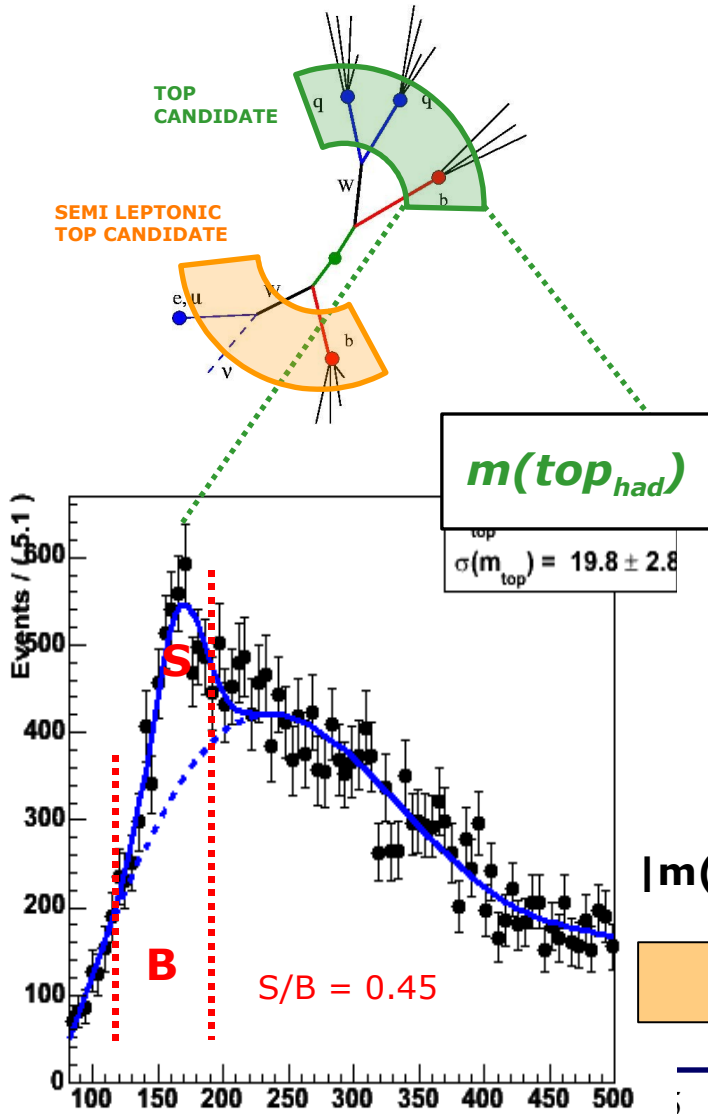

# Detector commissioning with top events

- Can also clean up sample by with requirement on  $m(jlv)$  [semi-leptonic top]

NB: There are two  $m(\text{top})$  solutions for each candidate due to ambiguity in reconstruction of  $p_z$  of neutrino

- Also clean signal quite a bit

$m(W)$  cut not applied here

# Early discoveries: $Z'$ , $G$

- Dilepton ( $ee$  or  $\mu\mu$ ) resonance with  $m \sim 1$  TeV :  
(current limits (depend on models)  $m_{Z'} > 600-700$  GeV)
  - $Z'$  generic for new heavy neutral gauge bosons (GUT, little Higgs, ...)
  - $G$  for massive particles foreseen in Extra Dimension theories
- « Easy discovery » :
  - signal = mass peak above low background : (Drell-Yan mainly)
  - Ldt needed for discovery ( $m_{Z'}=1$  TeV)  $\sim 0.07-0.70$  fb $^{-1}$  (depends on models)
  - Ldt needed for discovery ( $m_G=1$  TeV)  $\sim 4$  fb $^{-1}$  (with  $300$  fb $^{-1}$  discovery possible up to  $\sim 10$  TeV)
- More statistics needed to distinguish models (using :  $\sigma \cdot \Gamma$ , asymmetry, rapidity )

ATLAS, 100 fb $^{-1}$ ,  $m_G=1.5$  TeV

# Early discoveries :SUSY

Large  $\tilde{q}\tilde{q} \tilde{g}\tilde{g}$  cross-sections (for  $m(\tilde{q},\tilde{g}) \sim 1 \text{ TeV}$ )  $\Rightarrow \sim 100 \text{ evt/day}$  at  $10^{33}$

+ spectacular signature = **early discovery** ?

$M_0(\text{GeV})$

$$M_{\text{eff}}(\text{GeV}) = E_T^{\text{miss}} + E_T^{\text{lep}} + \sum_{j=1,4} p_{T,j}$$

# Strategy for background estimates

Background process (examples ....)	Control samples (examples ....)
$Z (\rightarrow \nu\nu) + \text{jets}$ $W (\rightarrow \tau\nu) + \text{jets}$ $t\bar{t} \rightarrow b\bar{t}b\bar{t}j$ QCD multijets	$Z (\rightarrow ee, \mu\mu) + \text{jets}$ $W (\rightarrow e\nu, \mu\nu) + \text{jets}$ $t\bar{t} \rightarrow b\bar{t}b\bar{t}$ lower $E_T$ sample

Can estimate background levels also varying selection cuts (e.g. ask 0,1,2,3 leptons ...)

A lot of data will most likely be needed!

normalization point

normalise MC to data at low  $E_T^{\text{miss}}$  and use it to predict background at high  $E_T^{\text{miss}}$  in "signal" region

Hard cuts against fake  $E_T^{\text{miss}}$ :

- reject beam-gas, beam-halo, cosmics
- primary vertex in central region
- reject event with  $E_T^{\text{miss}}$  vector along a jet or opposite to a jet
- reject events with jets in cracks
- etc. etc.

# Strategy for background estimates

- Obtain the  $E_T^{\text{miss}}$  distribution from data using top events

- By fixing the top mass in the leptonic channel, predict  $E_T^{\text{miss}}$
- Select top without b-tagging

- $E_T^{\text{miss}}$  for top signal minus sideband

- Reduce combinatorial background
- Normalise at low  $E_T^{\text{miss}}$ , where SuSy signals are small

- Add SuSy

- Repeat procedure with SuSy signal included
- $E_T^{\text{miss}}$  distribution from data
- Clear excess from SuSy at high  $E_T^{\text{miss}}$  observed: method works!

# SM Higgs signal

## Present limits :

direct searches(LEP)  $M_H > 114.4$  GeV

+ e.w. fit constraints  $M_H < 219$  GeV @ 95% CL

# SM Higgs signal significance

$S/\sqrt{B}$

$30 \text{ fb}^{-1}$  enough for SM Higgs discovery

Early discovery (with  $\sim 10 \text{ fb}^{-1}$ ):

- $M_H \sim 180 \rightarrow 600 \text{ GeV}$  easier  
mainly due to  $H \rightarrow 4l$
- $M_H < 180 \text{ GeV}$  more challenging:
  - $M_H \sim 115 \text{ GeV}$  in particular: observation of 3 channels needed to extract convincing signal in first year
  - $H \rightarrow l\nu l\nu$  high rate but no mass peak  $\Rightarrow$  not ideal for early discovery
- $M_H > 600 \text{ GeV}$   
 $H \rightarrow 4l$  limited statistically  
 $\Rightarrow$  use  $H \rightarrow ll \nu\nu, l\nu jj$

# SM Higgs with mass below 200 GeV

$m_H \sim 115 \text{ GeV}$   $10 \text{ fb}^{-1}$

total  $S/\sqrt{B} \approx 4^{+2.2}_{-1.3}$

ATLAS	$H \rightarrow \gamma\gamma$	$ttH \rightarrow ttbb$	$qqH \rightarrow qq\tau\tau$ ( $ll + l\text{-had}$ )
S	130	15	$\sim 10$
B	4300	45	$\sim 10$
$S/\sqrt{B}$	2.0	2.2	$\sim 2.7$

$\uparrow$  K-factors  $\equiv \sigma(\text{NLO})/\sigma(\text{LO}) = 2$  not included

Full GEANT simulation, simple cut-based analyses

# SM Higgs with mass below 200 GeV

## Remarks:

Each channel contributes  $\sim 2\sigma$  to total significance  $\rightarrow$  observation of all channels important to extract convincing signal in first year(s)

The 3 channels are complementary  $\rightarrow$  robustness:

- different production and decay modes
- different backgrounds
- different detector/performance requirements:
  - ECAL crucial for  $H \rightarrow \gamma\gamma$  (in particular response uniformity):  $\sigma/m \sim 1\%$  needed
  - b-tagging crucial for  $ttH$ : 4 b-tagged jets needed to reduce combinatorics
  - efficient jet reconstruction over  $|\eta| < 5$  crucial for  $qqH \rightarrow qq\tau\tau$ : forward jet tag and central jet veto needed against background

Note: -- all require "low" trigger thresholds

E.g.  $ttH$  analysis cuts:  $p_T(l) > 20$  GeV,  $p_T(\text{jets}) > 15-30$  GeV

-- all require very good understanding (1-10%) of backgrounds

# SM Higgs with mass below 200 GeV

$m_H \sim 130 \text{ GeV} \quad 10 \text{ fb}^{-1}$

$\lambda = e, \mu$

	$H \rightarrow \gamma\gamma$	$qqH \rightarrow qq\tau\tau$ ( $ll + l\text{-had}$ )	$H \rightarrow 4l$	$qqH \rightarrow qqWW$
S	120	$\sim 8$	$\sim 5$	18
B	3400	$\sim 6$	$< 1$	15
S/ $\sqrt{B}$	2.0	$\sim 2.7$	2.8	3.9

↑ K-factor = 2 not included ↑

total S/ $\sqrt{B} \approx 6$

- 4 complementary channels for physics and for detector requirements
- $S/\sqrt{B} < 3$  per channel (except  $qqWW$  counting channel) → observation of all channels important in first year
- $H \rightarrow 4l$  low rate but very clean: small background, narrow mass peak

Detector requirements:

- $\geq 90\%$   $e, \mu$  efficiency at low  $p_T$  (analysis cuts :  $p_T^{1,2,3,4} > 20, 20, 7, 7, \text{ GeV}$ )
- in particular low di-lepton LVL1 thresholds

# MSSM Higgs bosons $h, H, A, H^\pm$

$m_h < 135 \text{ GeV}$   
 $m_A = m_H = m_{H^\pm}$  at large  $m_A$

--  $A, H, H^\pm$  cross-section  $\sim \text{tg}^2\beta$   
 -- best sensitivity from  $A/H \rightarrow \tau\tau, H^\pm \rightarrow \tau\nu$   
 (not easy the first year ...)  
 --  $A/H \rightarrow \mu\mu$  experimentally easier  
 (esp. at the beginning)

Measurement of  $\text{tg} \beta$

- Large variety of channels and signatures accessible
- $bbA/H \rightarrow 4b$  is more difficult than at the Tevatron (because of huge QCD background)

# MSSM Higgs bosons $h, H, A, H^\pm$

Here only  $h$  (SM-like) observable at LHC, unless  $A, H, H^\pm \rightarrow \text{SUSY}$

$\rightarrow$  LHC may miss part of the MSSM Higgs spectrum

Observation of full spectrum may require high-E ( $\sqrt{s} \approx 2 \text{ TeV}$ ) Lepton Collider

# Conclusions

---

- LHC has potential for major discoveries already in the first year (months ?) of operation  
Event statistics : 1 day at LHC at  $10^{33}$   $\equiv$  1 year at previous machines for SM processes  
SUSY may be discovered "quickly", light Higgs more difficult ... and what about surprises ?
- Machine luminosity performance will be the crucial issue in first 1-2 years
- Experiments: lot of emphasis on test beams and on construction quality checks  
→ results indicate that detectors "as built" should give good starting-point performance.
- However: lot of data (and time ...) will be needed at the beginning to:
  - commission the detector and trigger in situ (and the software !!! ...)
  - reach the performance needed to optimize the physics potential
  - understand standard physics at  $\sqrt{s} = 14$  TeV and compare to MC predictions  
[ Tevatron (and HERA) data crucial to speed up this phase ... ]
  - measure backgrounds to possible New Physics (with redundancy from several samples ...)
- Efficient/robust commissioning with physics data in the various phases (cosmics, one-beam period, first collisions, ...), as well as solid preparation of MC tools, are our next challenges.  
Both are crucial to reach quickly the "discovery-mode" and extract a convincing "early" signal
